# optical tweezers<sup>1</sup>

1. the diameter of a trapped particle  
 $\gg$  the wavelength of light

2. the diameter of a trapped particle  
 $\ll$  the wavelength of light

# Electric dipole approximation

- 1). Induction by light (assume the dielectric particle is linear):

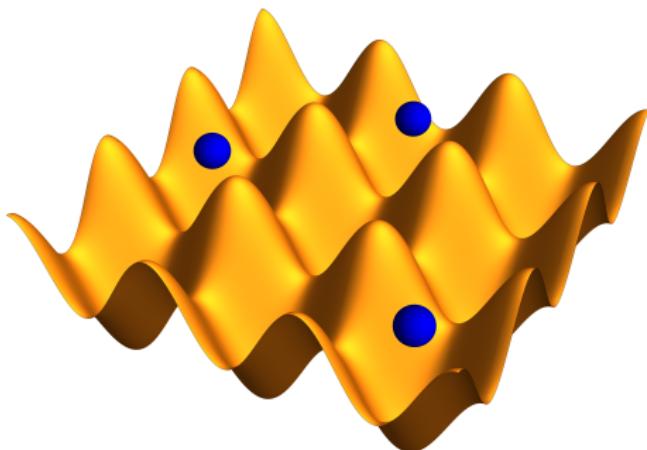

$$p = \alpha \cdot E_{light}$$

$p$  is the induced dipole moment,  $E_{light}$  is the electric field of the light, and  $\alpha$  is the polarizability of the atom

- 2). Gradient Force:

$$F_{gradient} = \nabla(p \cdot E_{light})$$

# AOD VS. SLM

## 1). Amplitude Object Design (AOD):

- *Operating Principle:* Uses acoustic waves to diffract and control light's amplitude.
- *Advantages:* Features high-speed modulation and scanning capabilities, low power consumption, and robustness for long-term use.
- *Limitations:* Restricted to amplitude modulation without phase control, possible noise from acoustic wave generation, and efficiency dependent on material properties.

## 2). Spatial Light Modulator (SLM):

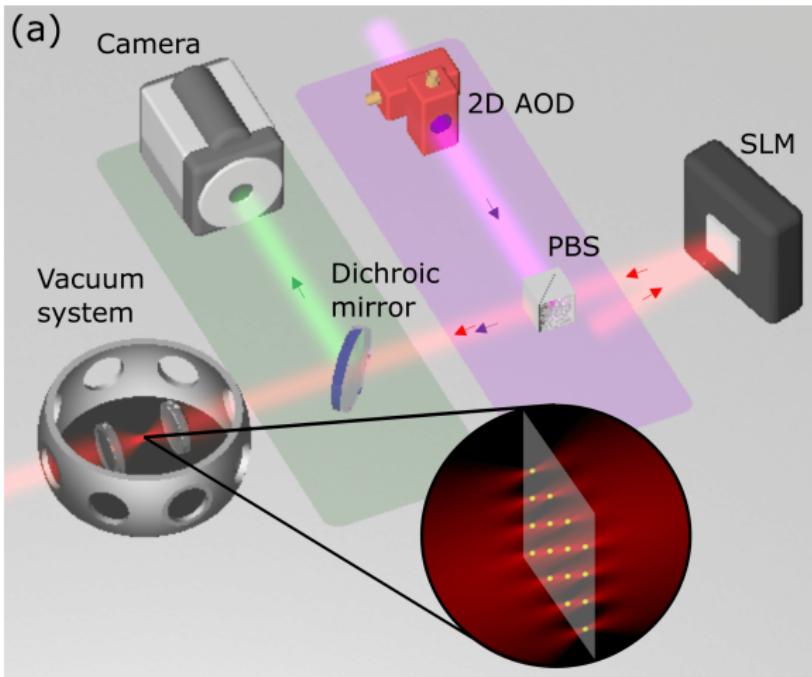

- *Operating Principle:* Modulates light's amplitude, phase, or polarization through an array of individually adjustable pixels, enabling complex light pattern generation.
- *Advantages:* Capable of intricate wavefront shaping and modulation across amplitude, phase, and polarization.
- *Limitations:* Higher complexity and cost, potential diffraction artifacts due to its pixelated nature, and limited refresh rate for dynamic applications.

## some confused words

- 1). qubit sites
- 2). a mean number of loading individual atoms
- 3). defect-free atomic qubit clusters

# readout

# single-qubit gate

- 1). *principle*: an optical laser field driving Raman transitions through an intermediate atomic state.
- 2). The atom-laser interaction is characterized by:
  - the Rabi frequency  $\Omega$  (its strength, proportional to the amplitude of the laser field)
  - the detuning  $\delta$  (the difference between the qubit resonance and the field frequencies)
  - the relative phase  $\varphi$
  - the duration  $\tau$
- 3). induces rotations around the  $(x, y, z)$  axes with angles  $(\Omega\tau \cos \varphi, \Omega\tau \sin \varphi, \delta\tau)$

# Rydberg blockade<sup>3</sup>

- 1). Van der Waals force,  $\propto R^{-6}$
- 2). dipole-dipole interaction,  $\propto R^{-3} \left( \vec{p}_1 \cdot \vec{p}_2 - 3(\vec{p}_1 \cdot \hat{R})(\vec{p}_2 \cdot \hat{R}) \right)$ , while  
 $\vec{p} = q \cdot \vec{d}$
- 3).  $r = \frac{n^2 \hbar^2}{k e^2 m}$ , while rydberg atoms in experiment  $50 \leq n \leq 70$
- 4). two closed atoms can't be  $|rr\rangle$
